### 22 Abstract

An eight-week feeding trial was conducted to examine the suitable dietary protein and lipid levels for juvenile hybrid sunfish (*Lepomis cyanellus*  $\mathcal{Q} \times Lepomis$  macrochirus  $\mathcal{O}$ ). A 5×2 factorial layout containing five protein levels (300, 340, 380, 420 and 460 g kg<sup>-1</sup>) and two lipid levels (30 and 80 g kg<sup>-1</sup>) were designed. Fish (initial body weight  $1.21 \pm$ 0.06 g) were fed the test diets twice daily. The final body weight (FBW) and percent weight gain (PWG) in fish increased with dietary protein level from 300 to 420 g kg<sup>-1</sup>, and afterward decreased with dietary protein level from 420 to 460 g kg<sup>-1</sup>. Feed intake and feed conversion ratio (FCR) significantly declined with increase dietary protein level. Fish fed at 380 and 420 g kg<sup>-1</sup> dietary protein level exhibited highest nitrogen retention efficiency (NRE) and phosphorus retention efficiency (PRE), however, the lowest nitrogen waste and phosphorus waste. For different dietary lipid levels, the higher FBW, PWG, NRE and PRE, but the lower feed intake, FCR, nitrogen and phosphorus waste, were found in fish fed diet fish fed at 80 g kg<sup>-1</sup> dietary lipid level than those in fish fed at 30 g kg<sup>-1</sup> dietary lipid level. At the end of feeding trail, the contents of body moisture and lipid significantly influenced by dietary lipid level. According to these results, a diet containing 420 g kg<sup>-1</sup> protein and 80 g kg<sup>-1</sup> lipid is recommended for efficient growth of juvenile hybrid sunfish. **KEY WORDS:** dietary lipid level, dietary protein level, hybrid sunfish, growth, feed

41 utilization, waste output

# **1 INTRODUCTION**

Protein and lipid in feed are essential nutrients for the normal growth and metabolism of fish. Dietary proteins provide amino acids for protein synthesis in fish (Glencross, Smith, Curnow, Smith, & Williams, 2001), and dietary lipids act as a source of energy fuel and essential fatty acids (Alam, Watanabe, Carroll, & Rezek, 2009). The ratio of protein to energy is one of the most important factors affecting feed utilization efficiency in fish (Rahimnejad, Bang, Park, Sade, Choi, & Lee, 2015), and protein-sparing action by elevating dietary lipid level has been reported in some fish species such as common dentex Dentex dentex (Skalli, Hidalgo, Abellán, Arizcun, & Cardenete, 2004), blunt snout bream Megalobrama amblycephala (Li, Liu, Jiang, Zhu, & Ge, 2010) and largemouth bass Micropterus salmoides (Huang, Wu, Lin, Chen, Karrow, Ren, & Wang, 2017). Generally, feeding at optimal dietary protein and lipid levels makes fish grow fast. Superfluous dietary protein increases feed cost and nitrogen waste output (Huang et al., 2017), and excess dietary lipid causes undesirable symptoms in fish such as fatty liver and poor fillet quality (Chatzifotis, Panagiotidou, Papaioannou, Pavlidis, Nengas, & Mylonas, 2010). Therefore, determination of dietary requirements for protein and lipid in fish helps in formulating cost-effective feed with high quality (Huang et al., 2017). Hybrid sunfish is a freshwater omnivore fish species that generated by hybridization of female green sunfish Lepomis cyanellus and male bluegill Lepomis macrochirus (Twibell, Wilson, Sanders, & Brown, 2003). Hybrid sunfish possesses some desirable characteristics like high flesh quality and good flavor, acceptance of prepared diets (Lane & Morris, 2002), and capacity for rapid growth under a wide range of water

65 temperature (Wang, Hayward, & Noltie, 2000), which make it as a good candidate for

66 commercial rearing. Although some studies tried to evaluate the experimental and

67 practice diets (Twibell et al., 2003) and effects of dietary protein levels on growth, feed 68 conversion and nitrogen utilization of juvenile hybrid sunfish (Tidwell, Webster, & 69 Clark, 1992), the optimum dietary protein and lipid levels for this species is still 70 unknown. In the present study, we examined the effects of different dietary protein and 71 lipid levels on feed intake, growth, feed utilization, body components and wastes output 72 of hybrid sunfish. Our objective was to determine the suitable dietary protein and lipid 73 levels for hybrid sunfish farming.

# 2 MATERIALS AND METHODS

## 76 2.1 Feed ingredients and experimental diets

Red fish meal (steam dried, manufactured in New Zealand), poultry by-product meal
(pet-feed grade, manufactured in the USA), menhaden fish oil (manufactured in the
USA), soybean meal, rapeseed meal, wheat flour, wheat bran and wheat gluten meal
were supplied by Kesheng Feed Company (Shaoxing, China). All the feed ingredients
were ground to pass through a 0.425 mm mesh before assay, and the proximate
composition of the feed ingredients is presented in Table 1.

Table 1

A 5×2 factorial layout containing five protein levels (300, 340, 380, 420 and 460 g kg<sup>-1</sup>) and two lipid levels (30 and 80 g kg<sup>-1</sup>) were designed, which correspondingly generated ten test diets. The diets contained low lipid level (30 g kg<sup>-1</sup>) and gradient protein levels (300, 340, 380, 420 and 460 g kg<sup>-1</sup>) were abbreviated as L30, L34, L38, L42 and L46, respectively, and the other five diets contained high lipid level (80 g kg<sup>-1</sup>) and gradient lipid levels were abbreviated as H30, H34, H38, H42 and H46, respectively. Red fish meal and soybean meal were used as the major protein source, and menhaden fish oil was used as the major lipid source.

#### Aquaculture Nutrition

The feed ingredients were weighed in accordance with the designed feed formula and mixed by hand gradually. After being mixed, blend of feed ingredients were further mixed with quantitative water (4:1 w/v) for 15 min. Pellets (0.5mm in diameter, 1.0 mm in length) were extruded using a single screw laboratory-scale extruder. The test diets were dried at 25 °C in an air-conditioned room, and were grinded into smaller pellets, and then stored in plastic bags at -20 °C until use. Formulation, proximate composition and gross energy of the test diets are presented in Table 2.

Table 2

### **2.2 Fish and feeding trial**

The feeding trial was conducted in Hangzhou Academy of Agricultural Sciences
(Hangzhou, China). Healthy hybrid sunfish juveniles hatched by Hangzhou Academy of
Agricultural Sciences were acclimated in two tanks (3 m in diameter, 1.5 m in height)
for two month. During the acclimation, the fish were fed with a commercial feed twice
daily.

Prior to the feeding trial, the acclimatized fish were deprived of feed for 24 h, thirty groups each of 30 fish were group-weighed and randomly distributed into 30 fiberglass tanks (100 L), with each test diet three replicates. The initial body weight of fish is 1.21  $\pm 0.06$  g (mean  $\pm$  SD, n = 30). Three groups each of 50 fish were sampled for the analysis of initial body composition, and the sampled fish were stored at -20 °C until analysis.

The feeding trial lasted eight weeks, during which fish were fed to apparent satiation with the test diets at 08:30 h and 16:30 h daily. Water in the experimental tanks was continually aerated and recirculated at 1.5 L/min, and 30% of water was renewed by aerated tap water every day. Water temperature was measured daily and averaged 28.5  $\pm 1.2$  °C. Dissolved oxygen was measured weekly, and always greater than 6.5 mg/L.

The concentration of NH<sub>3</sub>-N in the experimental tank was undetectable. At the end of the feeding trial, deprived of feed for 24 h, the fish were captured from each tank and bulk weighed. All of the fish from each tank were sampled for analysis of final body composition. After measurement of body weight, body length and liver weight, the sampled fish were stored at -20 °C for chemical analysis. 2.3 Chemical analysis Prior to chemical analysis, the sampled fish were thawed, weighed, autoclaved at 121 °C for 20 min, homogenized and dried at 105 °C. The contents of moisture, crude protein, crude lipid, ash and phosphorus of the feed ingredients, test diets and fish were analyzed following the methods described in AOAC (1995). **2.4 Calculations and statistics** Feed intake, percent weight gain (PWG), feed conversion ratio (FCR), retention efficiencies of nitrogen (NRE) and phosphorus (PRE), condition factor, hepatosomatic index, nitrogen waste and phosphorus waste are calculated as below: Feed intake (%/day) =  $100 \times I / [(W_0 + W_t) / 2 \times t]$ PWG (%) =  $100 \times (W_t / N_t - W_0 / N_0) / (W_0 / N_0)$  $FCR = I / (W_t - W_0 + W_d)$ NRE (%) =  $100 \times (W_t / N_t \times C_{Nt} - W_0 / N_0 \times C_{N0}) / [2 \times I / (N_t + N_0) \times C_{Nf}]$ PRE (%) =  $100 \times (W_t / N_t \times C_{Pt} - W_0 / N_0 \times C_{P0}) / [2 \times I / (N_t + N_0) \times C_{Pf}]$ Condition factor  $(g/cm^3) = 100 \times W_s / L_s^3$ Hepatosomatic index (%) =  $100 \times W_1 / W_s$ Nitrogen waste [g N/ (kg fish gain)] =  $1000 \times (I \times C_{Nf}) \times (1 - NRE) / (W_t - W_0)$ Phosphorus waste [g P/ (kg fish gain)] =  $1000 \times (I \times C_{Pf}) \times (1 - PRE) / (W_t - W_0)$ where I (g) is total amount of the dry feed;  $W_0$  (g) is total initial body weight and  $W_t$  (g) is total final body weight; W<sub>d</sub> (g) is total body weight of dead fish; t (d) is the duration 

#### Aquaculture Nutrition

of the trial;  $N_t$  is number of fish at the end of the trial and  $N_0$  is at the start;  $C_{Nt}$  (%) is nitrogen content of fish body at the end of the trial and  $C_{N0}$  (%) is at the start;  $C_{Nf}$  (%) is nitrogen content of test diets;  $C_{Pt}$  (%) is phosphorus content of fish body at the end of the trial and  $C_{P0}$  (%) is at the start;  $C_{Pf}$  (%) is phosphorus content of test diets;  $W_s$  (g),  $L_s$ (cm) and  $W_1$  (g) are body weight, total length and liver weight of the sampled fish, respectively.

The manipulation effects of protein level, lipid level and their interaction on final body weight, PWG, feed intake, FCR, NRE, PRE, condition factor, hepatosomatic index, whole body components (moisture, crude protein, crude lipid, ash and phosphorus), wastes of nitrogen and phosphorus of fish fed the test diets were tested by two-way ANOVA. Duncan's test was used to examine the differences in the above parameters between different dietary protein levels or between different dietary lipid levels if the interaction effect was not significant. To determine the diet with best production performance, one-way ANOVA and Duncan's test was conducted to examine the differences in above parameters among all the test diets. The significant level was set at P < 0.05. All the statistical analyses were performed with IBM SPSS. 

**3 RESULTS** 

### **3.1 Survival, growth, feed intake and feed utilization efficiency**

Survival rate ranged from 95% to 100% in the feeding trial. The FBW, PWG and feed intake were affected by dietary protein level and lipid level, while FCR, NRE and PRE were affected by dietary protein level, lipid level and their interaction (two-way ANOVA, P < 0.05, Table 3). The FBW and PWG in fish increased with dietary protein level increased from 300 to 420 g kg<sup>-1</sup>, and significantly higher FBW and PWG were found in fish fed at 80 g kg<sup>-1</sup> dietary lipid level than in fish fed at 30 g kg<sup>-1</sup> dietary lipid

167	level (Duncan's test, $P < 0.05$ ). The relationship between PWG and dietary crude
168	protein level (PL) was described as PWG = $-2.2425 \times (PL)^2 + 192.36 \times PL - 3115.3$ (P
169	$<$ 0.05, r² = 0.8272) at 30 g kg¹ dietary lipid level (Figure 1a), and PWG = $-3.765 \times$
170	$(PL)^2 + 315.64 \times PL - 5302.4$ ( <i>P</i> < 0.05, r <sup>2</sup> = 0.8141) at 80 g kg <sup>-1</sup> dietary lipid level
171	(Figure 1b). Feed intake and FCR declined with dietary protein level increased from
172	300 to 420 g kg <sup>-1</sup> (Duncan's test, $P < 0.05$ ), and significantly lower feed intake and FCR
173	were found in fish fed at 80 g $kg^{-1}$ dietary lipid level than in fish fed at 30 g $kg^{-1}$ dietary
174	lipid level (Duncan's test, $P < 0.05$ ). The highest NRE were found in fish fed at 380 and
175	420 g kg <sup>-1</sup> dietary protein levels (Duncan's test, $P < 0.05$ ), while the highest PRE were
176	found in fish fed at 380 g kg <sup>-1</sup> dietary protein levels (Duncan's test, $P < 0.05$ ).
177	Significantly higher PRE and NRE were found in fish fed at 80 g kg <sup>-1</sup> dietary lipid level
178	than in fish fed at 30 g kg <sup>-1</sup> dietary lipid level (Duncan's test, $P < 0.05$ ).
179	Table 3 and Figure 1
180	The FCR were significantly lower in fish fed diets H38, H42 and H46 than in fish
181	fed other test diets (one-way ANOVA, $P < 0.05$ ). The NRE and PRE were significantly
182	higher in fish fed diets H38 and H42 than in fish fed other test diets (Duncan's test, $P <$
183	0.05)
184	3.2 Morphology and body composition
185	At the end of the feeding trial, condition factor was affected by dietary lipid level and
185 186	At the end of the feeding trial, condition factor was affected by dietary lipid level and the interaction between protein level and lipid level (two-way ANOVA, $P < 0.05$ , Table
185 186 187	At the end of the feeding trial, condition factor was affected by dietary lipid level and the interaction between protein level and lipid level (two-way ANOVA, $P < 0.05$ , Table 4). The hepatosomatic index and body protein content were affected by dietary protein

204	kg <sup>-1</sup> dietary protein level (Duncan's test, $P < 0.05$ ). Condition factor and whole body
205	lipid content was lower in fish fed at 3% dietary lipid level than in fish fed at 80 g kg <sup>-1</sup>
206	dietary lipid level, while whole body moisture content was higher in fish fed at 30 g $kg^{-1}$
207	dietary lipid level than in fish fed at 80 g kg <sup>-1</sup> dietary lipid level (Duncan's test, $P <$
208	0.05).

#### 209

Higher condition factor was found in fish fed diet H46 than in fish fed diets L38, H30 and H42 (one-way ANOVA, P < 0.05), while no significant difference was found in condition factor among fish fed diets L30, L34, L42, L46, H34 and H38 (Duncan's test, P > 0.05).

214 **3.3 Wastes output** 

Table 4

The nitrogen waste and phosphorus waste were affected by dietary lipid level and protein level (two-way ANOVA, P < 0.05, Table 5). Nitrogen waste was lower in fish fed at 380 g kg<sup>-1</sup> dietary protein level than in fish fed at 300, 340 or 460 g kg<sup>-1</sup> dietary protein level, and phosphorus waste was lower in fish fed at 380, 420 and 460 g kg<sup>-1</sup> dietary protein level than in fish fed at 300 and 340 g kg<sup>-1</sup> dietary protein level (Duncan's test, P < 0.05). Higher nitrogen and phosphorus wastes were found in fish fed at 30 g kg<sup>-1</sup> dietary lipid level than in fish fed at 80 g kg<sup>-1</sup> dietary lipid level (Duncan's test, P < 0.05).

Table 5

#### 225 4 DISCUSSIONS

Tidwell et al. (1992) investigated the effects three isocaloric (4.0-4.2 Kcal g<sup>-1</sup>) diets containing varying dietary protein levels (260, 310 and 370 g kg<sup>-1</sup>) on growth and feed utilization of hybrid sunfish, and they found that higher PWG was observed in fish fed a diet containing 370 g kg<sup>-1</sup> protein than in fish fed diets containing 260 or 310 g kg<sup>-1</sup> protein. In the present study, the FBW and PWG in fish increased with dietary protein level from 300 to 420 g kg<sup>-1</sup>, whereas further elevation of dietary protein to 460 g kg<sup>-1</sup> led to a decline of growth performance. The regression equation indicated that the dietary protein level for maximum PWG was 429 g kg<sup>-1</sup> at 30 g kg<sup>-1</sup> dietary lipid level, and was 418 g kg<sup>-1</sup> at 80 g kg<sup>-1</sup> dietary lipid level, respectively. These results indicate that 420 g kg<sup>-1</sup> dietary protein could support the best growth of hybrid sunfish juveniles. This protein level is similar to the protein requirement (415.1-423.7 g kg<sup>-1</sup>) determined for the seed-parent of bluegill sunfish Lepomis macrochirus (Yang, Wang, Han, Yang, Li, & Jiang, 2016). Significantly higher FBW and PWG were found in fish fed at 80 g kg<sup>-1</sup> dietary lipid level than in fish fed at 30 g kg<sup>-1</sup> dietary lipid level, suggesting that 80 g kg<sup>-1</sup> dietary lipid level is more suitable for the fast growth of hybrid sunfish. This lipid level is as same as that (80 g kg<sup>-1</sup>) determined for juvenile bluegill sunfish *Lepomis* 

#### Aquaculture Nutrition

*macrochirus* (Hoagland, Davis, Tuan, & Mcgraw, 2003). Therefore, the optimal dietary
protein and lipid contents for fast growth of hybrid sunfish are 420 g kg<sup>-1</sup> and 80 g kg<sup>-1</sup>,
respectively.

In the present study, feed intake of hybrid sunfish declined with the increase of dietary protein and lipid levels. Similar results were found in Asian catfish Pangasius hypophthalmus (Liu, Wang, & Ji, 2011), Pseudobagrus ussuriensis (Wang, Ma, Shi, Liu, Guo, Yang, & Chen, 2012), giant croaker Nibea japonica (Chai, Ji, Han, Dai, & Wang, 2013) and hybrid grouper (Rahimnejad et al., 2015). In the present study, the FCR declined while the NRE and PRE enhanced with dietary protein level increased from 300 to 380 g kg<sup>-1</sup>, lower FCR but higher NRE and PRE were found in fish fed at 80 g kg<sup>-1</sup> dietary lipid level compared to fish fed at 30 g kg<sup>-1</sup> dietary lipid level, suggesting that the based on feed utilization efficiency, the optimal dietary protein and lipid levels for hybrid sunfish were respectively 380 g kg<sup>-1</sup> and 80 g kg<sup>-1</sup>. Besides, no statistically differences were found in FCR, NRE and PRE between fish fed dietary protein at 380 and 420 g kg<sup>-1</sup>. Thereby, the best feed utilization efficiency in hybrid sunfish was not impaired when fed at 420 g kg<sup>-1</sup> protein and 80 g kg<sup>-1</sup> lipid. According to the above mentioned results, the fast growth of hybrid sunfish is ascribed to high feed utilization rather than high feed intake. 

Lipid deposition in fish body is closely associated with dietary lipid level (Yi, Zhang, Xu, Li, Zhang, & Mai, 2014), increasing dietary lipid level generally result in an increment in whole body lipid while the shrinkage in whole body moisture. For instance, previous studies reported that the body lipid content increased with the dietary lipid level rose in various fish species, e.g. grouper *Epinephelus malabaricus* (Lin & Shiau, 2003), cobia *Rachycentron canadum* (Wang, Liu, Tian, Mai, Du, Wang, & Yang, 2005), Atlantic halibut *Hippoglossus hippoglossus* (Martins, Valente, & Lall, 2007),

white seabass *Atractoscion nobilis* (López, Durazo, Viana, Drawbridge, & Bureau,
2009; Jirsa, Deng, Davis, Wang, Hung, & Drawbridge, 2013), starry flounder *Platichthys stellatus* (Ding, Zhang, Wang, Ma, Meng, Duan, Sun, & Sun, 2010) and
shortfin corvina *Cynoscion parvipinnis* (González-Félix, Maldonado-Othón, &
Perez-Velazquez, 2016). In the present study, elevating dietary lipid level from 30 to 80
g kg<sup>-1</sup>, whole body lipid content increased and whole body moisture content declined,
while no significant difference was found in hepatosomatic index, suggesting enhancing
dietary lipid level will increase lipid deposition in body but not in liver of hybrid
sunfish.

nmental impacts should not be ignored when determining the optimal in and lipid levels for fish. In the present study, nitrogen waste and waste decreased with dietary lipid level raised from 300 to 380 g kg<sup>-1</sup>, and ly difference was detected in both nitrogen waste and phosphorus waste fed at 380 and 420 g kg<sup>-1</sup> dietary protein level although the values of it tended to increase with dietary protein level exceeding 380 g kg<sup>-1</sup>. , compared to fish fed at 30 g kg<sup>-1</sup> dietary lipid level, significantly lower trogen and phosphorus were found in fish fed at 80 g kg<sup>-1</sup> dietary lipid level. s indicate that feeding at optimal dietary protein and lipid levels could lecline wastes output in juvenile hybrid sunfish farming. To the best of our the effects of different dietary protein and lipid levels on wastes output in erely evaluated in a few fish species including giant croaker *Nibea japonica* 2013), golden pompano Trachinotus ovatus (Wang, Han, Wang, & Ma, rgemouth bass *Micropterus salmoides* (Huang et al., 2017). In the present astes output for hybrid sunfish fed at optimal combination of dietary protein re 42.54 g kg<sup>-1</sup> N and 8.26 g kg<sup>-1</sup> P, which is lower than that evaluated in

292	giant croaker (~50 g kg <sup>-1</sup> N, Chai et al., 2013), golden pompano (64 g kg <sup>-1</sup> N, Wang et
293	al., 2013) and largemouth bass (49.8 g kg <sup>-1</sup> N, 8.7 g kg <sup>-1</sup> P, Huang et al., 2017).
294	According to these results, it seems that hybrid sunfish farming may generate less
295	nitrogen and phosphorus wastes than that produced from the farming of giant croaker,
296	golden pompano and largemouth bass.
297	In conclusion, the FBW, PWG, NRE and PRE of hybrid sunfish increased, while
298	feed intake and FCR decreased, with dietary protein increased from 300 to 420 g kg <sup>-1</sup>
299	and dietary lipid increased from 30 to 80 g kg <sup>-1</sup> . Therefore, the optimal combination of
300	dietary protein and lipid for hybrid sunfish should be 420 g kg <sup>-1</sup> and 80 g kg <sup>-1</sup> ,
301	respectively. In fish fed diets containing 380-420 g kg <sup>-1</sup> protein and 80 g kg <sup>-1</sup> lipid, the
302	wastes output of nitrogen and phosphorus were obvious lower than that generated of
303	fish fed diets containing other combination of dietary protein and lipid. Feeding at
304	optimal combination of dietary protein and lipid is an efficient strategy to reduce waste
305	discharge in hybrid sunfish farming.
306	
307	ACKNOWLEDGEMENTS
308	This research is funded by the Public Welfare Project of Science Technology
309	Department of Zhejiang Province (Grant No. LGN19C190007) and the
310	Major Science and Technology Extension Project of Hangzhou Academy of Agricultura
311	l Sciences-Breeding and industrialization development of hybrid sunfish
312	(2016HNKT-01). The authors thank Mr. Kang Yang and Zhao Wei for their helps in
313	preparing the test diets.
